Application Name: Git Match

INFORMATION IN README

1. **Brief Application description:**

Our application is called "**git match**" with the aim to connect and create community among computer science students. Users will be able to make their own profile and attach their Github while also adding their own interests (outside and within a computer science lens). Our program will automatically look at their Github projects/profile and determine their strengths software wise to display on their profile. Users will have prompts to answer such as "Favorite programming language", "How many languages do you know", "What areas of computer science are you interested in?", etc. Users will also be able to add basic identifiable information such as pronouns, if they are looking for friends or studying, etc (A large amount of this content can already be retrieved from their github accounts). We will refrain from things like profile pictures or contact information until they end up connecting and if they choose to share it.

Once a profile is created users will be able to see a list of other users and click to see if they think they will want to connect with this user. Users will be able to talk to other users one on one if they end up matching with each other (although we would want to connect more people together we find that this may be an issue within the limited scope of our project and may encourage more meaningful friendships and networks.) If so they will be able to send a preface messaging saying they want to connect and the other user will receive a notification and can either accept or reject (the original user who sent the message will not be able to know if they said yes or not). From there if users connect they can message each other and share ideas or study!

2. **Contributors - In this case, it will be the team Members**

Team Name: Git Matchers
Meera Bipin
Wayne Chan
Mailie Voraphankit
Jessica Chhour
Stryder Lafone Demarois

Gaurav Joshi

3. **Technology Stack used for the project:**

Front End:

- HTML
- CSS
- JavaScript

Backend:

- Node.js

Database & Storage:

- PostgreSQL

Infrastructure & Hosting:

- Docker

4. **Prerequisites to run the application - Any software that needs to be installed to run the application:** Docker
5. **Instructions on how to run the application locally:**
    a. Git Clone to your own repository
    b. Install Node.js to your computer
    c. Open Terminal
    d. Navigate to the project folder using cd
    e. Install the dependencies: npm install
    f. Start the local development server: npm start
    g. Open the browser and go to the local address provided.
6. **How to run the tests: Lab 10**
7. **Link to the deployed application: Later Labs**

Application Description

Our application is called "**git match**" with the aim to connect and create community among computer science students. Users will be able to make their own profile and attach their Github while also adding their own interests (outside and within a computer science lens). Our program will automatically look at their Github projects/profile and determine their strengths software wise to display on their profile. Users will have prompts to answer such as "Favorite programming language", "How many languages do you know", "What areas of computer science are you interested in?", etc. Users will also be able to add basic identifiable information such as pronouns, if they are looking for friends or studying, etc (A large amount of this content can already be retrieved from their github accounts). We will refrain from things like profile pictures or contact information until they end up connecting and if they choose to share it.

Once a profile is created users will be able to see a list of other users and click to see if they think they will want to connect with this user. Users will be able to talk to other users one on one if they end up matching with each other (although we would want to connect more people together we find that this may be an issue within the limited scope of our project and may encourage more meaningful friendships and

networks.) If so they will be able to send a preface messaging saying they want to connect and the other user will receive a notification and can either accept or reject (the original user who sent the message will not be able to know if they said yes or not). From there if users connect they can message each other and share ideas or study!

Audience

Computer Science Students looking to find friends that may match their skills and interests. Users can use this app to find people to do projects with, or just find people to study and be friends with.

Vision Statement

“For computer science students who are looking for fellow computer science students to befriend and work with. Git Match is an app that allows users to create profiles with relevant information in regards to computer science, where they can match with fellow members to work on projects with. Unlike Wizz, our product allows users to include specific information in regards to computer science, tailored to their needs and interests.”

Developmental Methodology:

Weekly Scrum on Wednesdays before we meet as a team on Thursdays.
To-do list where we can add stickies with to-do, in-progress, and complete
Use feature requests instead of a Kanban board

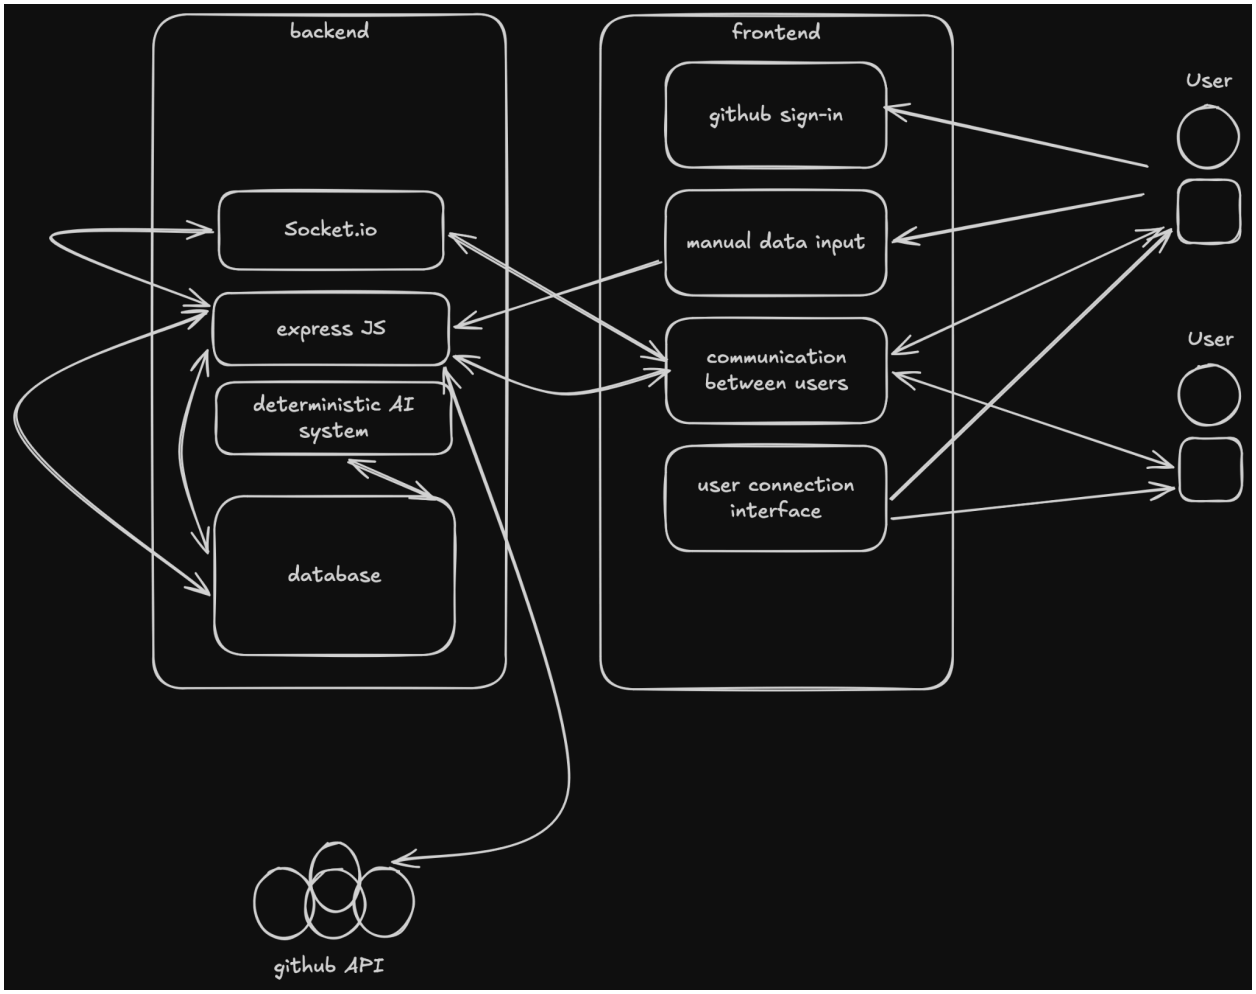

Communication Plan

Our team plans to use Discord as our primary form of communication. We plan to do weekly check-ins on Wednesdays in chat in order to make sure that we’re staying on track before we meet in person on Thursdays. In addition, all updates will also be shared via Discord through different channels we have.

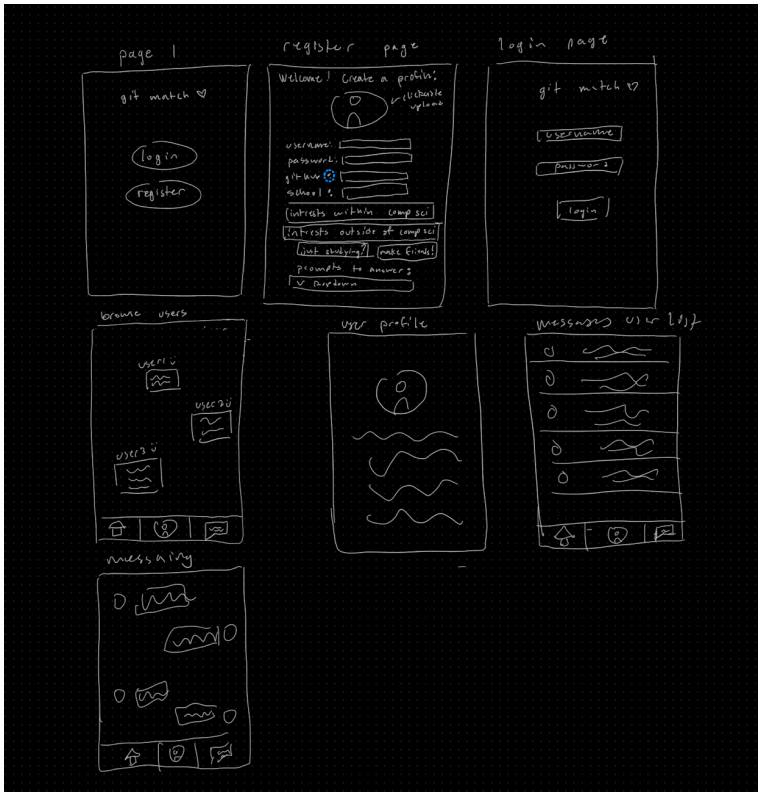

Meeting Plan

- Team meeting: Wednesdays at 5:00pm on Zoom/Discord
- Weekly meeting with TA: Thursdays during lab

Wire Frame

Issues we could encounter

- Someone could DDoS us, and since the tools we use require a lot of processing power, inference for different accounts could cost us a lot of computation.
    - We can fix this with the built-in GitHub account validation in most web apps
- People might not trust us with their data, and so will prevent us from accurately providing matches and will fail to build momentum
    - As they use the app, the less they need it, add some messaging services and stuff like that with minimal image and rich text usage in order to prevent sexual harassment
- Social apps can face challenges with safety and any type of harassment, so putting in guardrails to make sure people are safe is integral.
